

2nd interview to Pramudu

On Api

1.What is an API really?

ans(pramudu): digital information, from frontend to backend and frontend to server, from server side to frontend, so i can see what's happening.

2. What problem was the API invented to solve?

Ans(pramudu): for any two system to communicate, or there any bridge between any system.

3. Imagine APIs disappear tomorrow.

What breaks first?

Ans(pramudu): If APIs breaks, let's say there's button and image anything that is , there's for user, even if we click, it will have no response.

4.Suppose your React frontend needs user data.

Without APIs, how would the frontend get that data?\

Ans(pramudu): you can take the input, but how you gonna save it if there's no API

5. Can two systems communicate without an API?

If yes, how?

If no, why not?

Ans(pramudu): No, the whole idea of API is communication between two system. The functionality of API is like to take request first then respond to that request, so API is design that way so if there is true meaning is communicate, so while taking about computer system how will that happen if there's no system design for a communication

6. If APIs are just communication channels,
why not connect the frontend directly to the database?

Ans(pramudu): database is more organised on raw data, let's take a example of restaurant, let's say there's a user comes to restaurant, the user would communicate and order the waiter, then the waiter goes inside and place an order, chef inside the kitchen would be like backend, then it prepare food, then if backend need any ingredient's it goes to database, so the way it design the user would not directly go to restaurant inventory and then cook, so as per the qs the compute is yet to happen, what to compute, the data from the database needs some logic to be computed as per the data, data and logic would not work without compute.

7. Why does ChatGPT mobile app need an API?

Why can't the app directly talk to the model?

Ans(pramudu): ChatGPT need API, so whatever we input our query, it has to be processed, and computed in the backend where logic happens, and it needs server, compute need to happens, and the hardware which is not in our device, that message, text, image, input needs to go to the server side, go through computational process that request we send comes back to us as a respond, all this process need API, since it's a system to system communicational process.

Any app can't directly talk with the model, is one of the issues is security issues, security vulnerability, if it would happen directly, it would be more chaotic, the response would not be as the logical and organized, it kind of saying why can't in restaurant a user can't go directly to the kitchen or inventory,
